

Decode finds the right tire 87% of the time, but auto-verifies 0%. That is the gap to close.

15 FRESH tire codes through the live pipeline this week (new codes each run, so the cache cannot fake the speed). It identified the correct brand 87% of the time, but auto-verified 0% - every found tire was routed to needs-review as a "suggestion" instead of being counted. False auto-counts: 0 (safe). The gap is the verify gate, not the finding.

Decode spend this run: about \$0.011 for 16 codes (mini models: 7 firecrawl credits, 1 gemini, 1 openai calls). Codes already in your database cost \$0.

WHAT TO DO

DO NOW

- high

Lean on the live 52k catalog as the primary path. Your global catalog (52,359 tires) is deployed and wired into resolution. A tire already in it should resolve INSTANTLY with the exact size at \$0 and no AI. Confirm this is firing live: if most scans hit the catalog, the "decode anything in seconds" speed is back immediately.
- high

Make the AI decode fast for catalog misses. For tires NOT in the catalog, the size currently fills in about 8 to 10 seconds in the background. Tighten it (faster grounded model, return on the first valid size) so a full result lands in 2 to 3 seconds like before.

DO NEXT

- med

One branch, backed up. Settle on tire-barcode-db (it is deployed and has everything), commit the loose ends, and push to GitHub. Retire the parallel decoder-hardening-v1-local so the project stops feeling tangled.
- low

Focus the agents and auto-catch regressions. Consolidate the 27 overlapping advisory agents to the high-value set, and add a decode-accuracy regression tracker so this weekly report flags "are we going backwards?" automatically before you feel it.

DO LATER

- low

Re-validate and lock it in. After the catalog and speed work, re-run the 100-tire validation to prove the verify rate jumped and the speed is back. This report becomes the dashboard for it.

BEFORE YOU FORGET

105 files uncommitted and 76 commits unpushed on tire-barcode-db. Push when you are ready.
